A Simple Task for Pandas-DataFrame:

Dataset under discussion - Sample URL:

https://github.com/ShahzadSarwar10/FULLSTACK-WITH-AI-BOOTCAMP-B1-MonToFri-2.5Month-Explorer/blob/main/DataSetForPractice/RealEstate-USA.csv

It is REAL ESTATE - US data.

TASK:

1. Load above CVS file above, into DataFrame variable, with Pandas, following columns With default – auto indexing.

Print DataFrame.

2. Call following method/properties of DataFrame, print output and analyze the output.

.info()

.dtypes

.describe()

.shape

3. Explore

https://www.geeksforgeeks.org/python-pandas-dataframe-to_string/

Use , DataFrame method - .to_string()

Use, debug, trace and play with following paramters.

Parameters:

- ✓ buf: Buffer to write the output string to (e.g., a file). Defaults to None, which means the output is returned as a string.
- ✓ columns: Specifies a subset of columns to include in the output. If None, all columns are printed.
- ✓ col_space: Defines the minimum width of each column.
- ✓ header: Whether to print column names. Can also accept a list of column name aliases.
- ✓ index: Whether to include index labels. Default is True.
- √ na_rep: String representation for missing values (NaN). Default is 'NaN'.
- ✓ formatters: Dictionary or list of functions to apply to columns for formatting their output.
- ✓ float format: Formatter function to apply specifically to floating-point numbers.
- ✓ sparsify: Controls hierarchical index formatting. If False, prints every multi-index key at each row.
- ✓ index names: Whether to print index names. Default is True.
- ✓ justify: Alignment of column headers ('left', 'right', 'center', 'justify' or 'justify-all').
- ✓ max rows: Maximum number of rows to display. If exceeded, truncates output.
- √ max cols: Maximum number of columns to display. If exceeded, truncates output.
- ✓ show dimensions: If True, displays the shape (rows x columns) of the DataFrame.
- ✓ decimal: Specifies the character for decimal separation (e.g., ',' for European formatting).
- ✓ line_width: Defines the maximum character width of a row before wrapping text."""
- 4. On given DataFrame select top 7 rows, and print

- 5. On given DataFrame select bottom 9 rows, and print
- 6. On Given DataFrame access the Name column for "city" and print whole column Then next, access the name column for "street" and print whole column
- 7. On Given DataFrame access access multiple columns like "street" and "city" Print it

Reference:

https://www.datacamp.com/tutorial/loc-vs-iloc

- Selecting a single row using .loc
 With index value 5 , print the returned row and analyze results.
- Selecting multiple rows using .loc
 With index value 3 and 5 , 7 , print the returned rows and analyze results.
- Selecting a slice of rows using .loc
 With index value range of 3 and 9, print the returned row and analyze results.
- Conditional selection of rows using .loc "price" greater then "100000" , print the returned row and analyze results.
- Conditional selection of rows using .loc "city" equal to "Adjuntas" , print the returned row and analyze results.
- 13. Conditional selection of rows using .loc "city" equal to "Adjuntas" and "price" is equal to - less then 180500 , print the returned row and analyze results.
- 14. Selecting a single column using .loc
 With index value 7, only select following columns
 "city","price", "street", "zip_code", "acre_lot",
 print the returned row and analyze results.
- 15. Selecting a slice of columns using .loc Form "city" to "zip_code" , print the returned row and analyze results.
- 16. Combined row and column selection using .loc "city" equal to "Adjuntas" and Form "city" to "zip_code" , print the returned row and analyze results.

- Selecting a single row using .iloc
 Select 5th row
 , print the returned row and analyze results.
- 18. Selecting multiple rows using .iloc Select – 7th row, 9th row and 15th row , print the returned row and analyze results.
- Selecting a slice of rows using .iloc
 Select from 5th to 13th row
 , print the returned row and analyze results.
- Selecting a single column using .iloc
 Select 3rd column
 , print the returned row and analyze results.
- 21. Selecting multiple columns using .iloc Select 2nd column, 4th column, 7th columns , print the returned row and analyze results.
- 22. Selecting a slice of columns using .iloc Range: Select from 2nd column to 5th columns , print the returned row and analyze results.
- 23. Combined row and column selection using .iloc Select 7th row, 9th row and 15th row Select 2nd column, 4th column , print the returned row and analyze results.
- 24. Combined row and column selection using .iloc Select range: 2nd row, 6th row Select range: 2nd column to 4th column , print the returned row and analyze results.
- 25. Add a New Row to a Pandas DataFrame print the returned dataFrame and analyze results.
- 26. delete row with index 2 print the returned dataFrame and analyze results.
- 27. delete row with index from 4 to 7th row print the returned dataFrame and analyze results.

- 28. Delete "house_size" column print the returned dataFrame and analyze results.
- 29. Delete "house_size" and "state" columns print the returned dataFrame and analyze results.
- 30. Rename column "state" to "state_Changed"
 Print the returned dataFrame and analyze results.
- 31. Rename label from 3 to 5
 Print the returned dataFrame and analyze results.
- 32. query() to Select Data where: "price" < 127400"city" not equal to "Adjuntas"Print the returned dataFrame and analyze results.
- 33. sort DataFrame by price in ascending order column "price"
- 34. "group the DataFrame by the "city" column and calculate the sum of "price" for each category Print the returned dataFrame and analyze results.
- 35. use dropna() to remove rows with any missing values Print the returned dataFrame and analyze results.
- 36. filling NaN values with 0
